LoopSight — Water Capture Sheet (10–15 borderline pairs)

Goal: settle conditional_benefit with REAL photos — only borderline samples where YOU hesitate. Two lightings per sample. Stop after 10–15 good pairs.

Safety: Turbidity is NOT potability. Clear-looking water can still carry arsenic/fluoride/nitrate. This sheet is for screening research only.

Flag visibly cloudy water for follow-up. Do NOT label any sample as safe to drink — visible turbidity: do not drink without treatment.

How to shoot (same for every sample):

1. Place checkerboard behind clear glass, 2–3 cm gap. Glass on white paper, no faces in frame. Frame tightly on glass+pattern.
2. Pour sample. For borderline: water where YOU hesitate at a glance (hazy? settling? could be glass?). Skip obvious clear/muddy — they prove nothing.
3. Photo A — ambient light (room light, no flash). Photo B — backlight (hold phone flash/torch behind glass) OR phone flash from front. Keep distance/angle identical.
4. BEFORE running app: write hesitation note + self-guess (clear / probably-fine / concerning). After app, compare — did its uncertainty match your reason?
5. Save as: sample03_ambient.jpg + sample03_backlight.jpg (or _flash). Keep pairs together. No editing/cropping after.

Log — fill as you shoot (pen, one line each):

ID	Hesitation — why you hesitated (one line)	Self-guess BEFORE app	A: amb	B: back/flash	App UNCERTAIN?	App vis.	Match?	Notes
01		*clear / prob-fine / concerning*

After shooting — run (from repo root):

python services/inference/scripts/calibrate_thresholds.py data/self_captured → copy suggested thresholds if needed

python services/inference/scripts/run_experiments.py data/self_captured --profile water_turbidity_v1 → read conditional_benefit (on REAL borderline pairs)

How to read the answer:

• conditional_benefit > 0 means second look (backlight/flash) genuinely resolved cases where ambient alone was borderline — claim holds.

• ~0 or negative on REAL borderline means mechanism didn't help — keep domain, pitch honest negative result + execution (also strong).

• App UNCERTAIN? should line up with your hesitation note — if not, thresholds need recalibration, not a pivot.

Keep this sheet with the dataset — it's the audit trail that your "borderline" was a real human hesitation, not a vibe.
